

U.S. Equity S-Factor Feed

Universe: 4,400+ Equities

Data Delivery: CA's data feeds are available 24*7 in real time through a RESTful JSON and XML API or as FTP files. The data can be packaged at different frequencies ranging from 1-minute updates to daily snapshots.

S-Factor Feed Field Descriptions

Column Name	Description
Ticker	Twitter product symbol
Date	Date and time of sentiment estimate (UTC)
Raw-S	Raw-S is the summation of sentiment of unique tweets received from credible accounts in a rolling 24-hour window at the time of observation. For e.g., at 09:10 AM, it is the summation of sentiment of tweets received between 09:10 AM the previous day and 09:10 AM today. Similarly, at 09:11 AM, it is the summation of sentiment of tweets received between 09:11 AM the previous day and 09:11 AM today.
Raw-S-Mean	Raw-S-Mean is the 20-day moving average of Raw-S at the time of observation. E.g.- At 09:10, it is the average of 20 historical Raw-S values at 09:10 (including present value). At 15:40, it is the average of 20 historical Raw-S values at 15:40.
Raw-Volatility	Raw-Volatility is the 20-day moving standard deviation of Raw-S at the time of observation. E.g.- At 09:10, it is the standard deviation of 20 historical Raw-S values at 09:10 (including present value). At 15:40, it is the standard deviation of 20 historical Raw-S values at 15:40.
Raw-Score	This is the statistical Z-Score of Raw-S at the observation time At 09:10, for e.g. $RawScore_{09:10} = \frac{RawS_{09:10} - RawSMean_{09:10}}{RawSVolatility_{09:10}}$ At 09:11, we would use $RawScore_{09:11} = \frac{RawS_{09:11} - RawSMean_{09:11}}{RawSVolatility_{09:11}}$
S	Similar to Raw-S. The key difference here is that S is the exponentially time weighted summation of tweets in the 24-hour window. Tweets arriving closer to the observation time have a higher weight than the tweets arriving farthest from observation window.
S-Mean	The 20-day moving average of S at the time of observation. E.g.- At 09:10, it is the average of 20 historical S values at 09:10 (including present value). At 15:40, it is the average of 20 historical S values at 15:40. The 20-day mean provides a baseline to calculate a S-Score.
S-Volatility	The 20-day moving standard deviation of S at the time of observation. E.g.- At 09:10, it is the standard deviation of 20 historical S values at 09:10 (including present value). At 15:40, it is the standard deviation of 20 historical S values at 15:40.
S-Score	Normalized value of S. This is CA's S-Score™

	This is the statistical Z-Score of <i>S</i> at the observation time At 09:10, for e.g. $SScore_{09:10} = \frac{S_{09:10} - SMean_{09:10}}{SVolatility_{09:10}}$ At 09:11, we would use $SScore_{09:11} = \frac{S_{09:11} - SMean_{09:11}}{SVolatility_{09:11}}$
S-Volume	Indicative Tweet volume used to compute the sentiment estimate. This is the number of unique tweets arriving in a 24-hour interval from certified CA accounts.
SV-Mean	20 day moving average of <i>S-Volume</i> at the time of observation. The <i>SV-mean</i> provides a base line for calculating <i>SV-Score</i>.
SV-Volatility	20 day moving standard deviation of <i>S-Volume</i> at the time of observation
SV-Score	Normalized value of <i>S-Volume</i> A Z-score of the <i>S-Volume</i>, computed like <i>Raw-Score</i> and <i>S-Score</i>
S-Dispersion	Measure of the Tweet source diversity contributing to a sentiment estimate. At the time of observation, it is calculated as $SDispersion = \frac{\# \text{ Unique Accounts}}{SVolume}$
S-Buzz	A measure of unusual volume activity compared to a universe of stocks. Provides a cross sectional view of unusual Twitter activity at the observation time.
S-Delta	Change in <i>S-Score</i> over a 15-min lookback period. $SDelta_{09:10} = SScore_{09:10} - SScore_{08:55}$ $SDelta_{09:11} = SScore_{09:11} - SScore_{08:56}$
Center-Date	Date of sentiment estimate in US/Eastern time-zone
Center-Time	Time of sentiment estimate in US/Eastern time-zone (Daylight Savings Adjusted-09:30 AM is always the open)
Center-Time-Zone	Center time-zone (US/Eastern)
